

COMPOSITIONS AND METHODS FOR CYSTIC FIBROSIS THERAPY

CROSS-REFERENCE TO RELATED APPLICATION

Sub
A1

5 This application is a continuation-in-part of U.S. Serial Number 08/951,912, filed October 16, 1998.

TECHNICAL FIELD

10 The present invention relates generally to the treatment of cystic fibrosis. The invention is more particularly related to compositions comprising one or more compounds such as flavones and/or isoflavones, which may be used to activate chloride transport (*i.e.*, absorption and/or secretion) in epithelial tissues of the airways, the intestine, the pancreas and other exocrine glands, and for cystic fibrosis therapy.

15

BACKGROUND OF THE INVENTION

15 Cystic fibrosis is a lethal genetic disease afflicting approximately 30,000 individuals in the United States. Approximately 1 in 2500 Caucasians is born with the disease, making it the most common lethal, recessively inherited

20 disease in that population.

25 Cystic fibrosis affects the secretory epithelia of a variety of tissues, altering the transport of water, salt and other solutes into and out of the blood stream. In particular, the ability of epithelial cells in the airways, pancreas and other tissues to transport chloride ions, and accompanying sodium and water, is severely reduced in cystic fibrosis patients, resulting in respiratory, pancreatic and intestinal ailments. The principle clinical manifestation of cystic fibrosis is the resulting respiratory disease, characterized by airway obstruction due to the presence of a thick mucus that is difficult to clear from airway surfaces. This thickened airway liquid contributes to recurrent bacterial infections and progressively impaired

30 respiration, eventually resulting in death.

FOOTNOTES

In cystic fibrosis, defective chloride transport is generally due to a mutation in a chloride channel known as the cystic fibrosis transmembrane conductance regulator (CFTR; *see* Riordan et al., *Science* 245:1066-73, 1989). CFTR is a linear chloride channel found in the plasma membrane of certain epithelial cells, where it regulates the flow of chloride ions in response to phosphorylation by a cyclic AMP-dependent kinase. Many mutations of CFTR have been reported, the most common of which is a deletion of phenylalanine at position 508 (Δ F508-CFTR), which is present in approximately 70% of patients with cystic fibrosis. A glycine to aspartate substitution at position 551 (G551D-CFTR) occurs in approximately 1% of cystic fibrosis patients.

Current treatments for cystic fibrosis generally focus on controlling infection through antibiotic therapy and promoting mucus clearance by use of postural drainage and chest percussion. However, even with such treatments, frequent hospitalization is often required as the disease progresses. New therapies designed to increase chloride ion conductance in airway epithelial cells have been proposed, but their long term beneficial effects have not been established and such therapies are not presently available to patients.

Accordingly, improvements are needed in the treatment of cystic fibrosis. The present invention fulfills this need and further provides other related advantages.

SUMMARY OF THE INVENTION

Briefly stated, the present invention provides compositions and methods for enhancing chloride transport in epithelial cells and for the therapy of cystic fibrosis. Within one aspect, the present invention provides methods for enhancing chloride transport in epithelial cells, comprising contacting epithelial cells with a compound selected from the group consisting of flavones and isoflavones, wherein the compound is capable of stimulating chloride transport and wherein the compound is not genistein. Within certain embodiments, the compound is (a) a polyphenolic compound having the general formula:

or

wherein carbon atoms at positions 2, 3, 5, 6, 7, 8, 2', 3', 4', 5' and 6' are bonded to a moiety independently selected from the group consisting of hydrogen atoms, hydroxyl groups and methoxyl groups, and wherein X is a single bond or a double bond; or (b) a stereoisomer or glycoside derivative of any of the foregoing polyphenolic compounds. Such compounds include, within certain embodiments, quercetin, apigenin, kaempferol, biochanin A, flavanone, flavone, dihydroxyflavone, trimethoxy-apigenin, apigenin 7-O-neohesperidoside, fisetin, rutin, daidzein and prunetin. For enhancing chloride transport in airway epithelial cells of a mammal, compounds may be administered orally or by inhalation. Other epithelial cells that may be employed include intestinal, pancreas, gallbladder, sweat duct, salivary gland and mammary epithelial cells. Within certain embodiments, the compound is combined with a substance that increases expression of a CFTR; and/or a chemical chaperone that increases trafficking of a CFTR to the plasma membrane.

Within other aspects, methods for enhancing chloride transport in epithelial cells may comprise contacting epithelial cells with a compound selected from the group consisting of resveratrol, ascorbic acid, ascorbate salts and dehydroascorbic acid. Such compounds may further be used in combination with a flavone or isoflavone as provided above.

Within other aspects, the present invention provides methods for treating cystic fibrosis in a patient, comprising administering to a patient a compound as described above, wherein the compound is capable of stimulating chloride transport. Within certain embodiments, the compound is genistein, quercetin, apigenin, kaempferol, biochanin A, flavanone, flavone, dihydroxyflavone, trimethoxy-apigenin, apigenin 7-O-neohesperidoside, fisetin, rutin, daidzein or prunetin. Within other embodiments, the compound is resveratrol, ascorbic acid, ascorbate salts and dehydroascorbic acid. Such compounds may be administered alone or in combination. Compounds may be administered orally or by inhalation. Within certain embodiments, the compound is combined with a substance that increases expression of a CFTR; and/or a chemical chaperone that increases trafficking of a CFTR to the plasma membrane.

Within further related aspects, the present invention provides methods for increasing chloride ion conductance in airway epithelial cells of a patient afflicted with cystic fibrosis, wherein the patient's CFTR protein has a deletion at position 508, the method comprising administering to a mammal one or more compounds as described above, wherein the compound is capable of stimulating chloride secretion in the airway epithelial cells.

Within still further related aspects, the present invention provides methods for increasing chloride ion conductance in airway epithelial cells of a patient afflicted with cystic fibrosis, wherein the patient's CFTR protein has a mutation at position 551, the method comprising administering to a mammal one or more compounds as described above, wherein the compound is capable of stimulating chloride secretion in the airway epithelial cells.

Within further aspects, pharmaceutical compositions for treatment of cystic fibrosis are provided, comprising (a) one or more flavones or isoflavones capable of stimulating chloride transport and (b) one or more of: (i) a compound that increases expression of a CFTR in an epithelial cell; and/or (ii) a chemical chaperone that increases trafficking of a CFTR to a plasma membrane in an epithelial cell; and; and in combination with a pharmaceutically acceptable carrier. Within certain embodiments, the flavone or isoflavone may be genistein, quercetin,

apigenin, kaempferol, biochanin A, flavanone, flavone, dihydroxyflavone, trimethoxy-apigenin, apigenin 7-O-neohesperidoside, fisetin, rutin, daidzein and/or prunetin, in combination with a pharmaceutically acceptable carrier.

Within still further aspects, a pharmaceutical composition for treatment of cystic fibrosis may comprise: (a) a polyphenolic compound having the general formula:

or

wherein carbon atoms at positions 2, 3, 5, 6, 7, 8, 2', 3', 4', 5' and 6' are bonded to a moiety independently selected from the group consisting of hydrogen atoms, hydroxyl groups and methoxyl groups, and wherein X is a single bond or a double bond; or a stereoisomer or glycoside derivative of any of the foregoing polyphenolic compounds; (b) a compound selected from the group consisting of resveratrol, ascorbic acid, ascorbate salts and dehydroascorbic acid; and (c) a physiologically acceptable carrier.

These and other aspects of the present invention will become apparent upon reference to the following detailed description and attached drawings. All references disclosed herein are hereby incorporated by reference in their entirety as if each was incorporated individually.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a recording of transepithelial short-circuit current (Y axis) as a function of time (X axis), showing the effect of apigenin on the current across a Calu-3 cell monolayer. Measurements were performed in an Ussing chamber, where the basolateral membrane was permeabilized with α -toxin and a chloride gradient was applied across the apical membrane as a driving force. Tissue was first stimulated with cAMP (100 μ M). Apigenin (50 μ M) was subsequently added as indicated. The horizontal bar represents 100 seconds, and the vertical bar represents 12 μ A/cm².

Figure 2 is a recording showing the effect of quercetin on transepithelial short-circuit current across a Calu-3 cell monolayer in an Ussing chamber, where the basolateral membrane was permeabilized with α -toxin and a chloride gradient was applied across the apical membrane as a driving force. Tissue was first stimulated with cAMP (100 μ M). Quercetin (30 μ M) was subsequently added as indicated. Bars are 140 seconds (horizontal) and 12 μ A/cm² (vertical).

Figure 3 is a recording illustrating the dose-dependent stimulation of transepithelial chloride secretion by quercetin (in the amounts indicated) across a primary bovine tracheal epithelium. Amiloride (50 μ M) was added to block sodium transport as indicated. The CFTR channel blocker diphenylcarboxylate (DPC, 5 mM) was added as shown.

Figure 4 is a recording showing the effect of biochanin A on transepithelial short-circuit current across a Calu-3 cell monolayer in an Ussing chamber, where the basolateral membrane was permeabilized with α -toxin and a chloride gradient was applied across the apical membrane as a driving force. The tissue was first stimulated with forskolin (Fsk, 10 μ M). Subsequent addition of biochanin A (Bio, 100 and 300 μ M) was subsequently added as indicated.

Figure 5 is a cell-attached single channel patch clamp recording from a 3T3 cell expressing Δ F508-CFTR. The cell was treated with 10 μ M forskolin as shown. Genistein (50 μ M) and apigenin (50 μ M), were added where indicated by boxes. The holding potential was 75 mV, and channel openings were upward.

Figure 6 is a whole cell patch clamp recording on an airway epithelial cell homozygous for $\Delta F508$ -CFTR. Before the measurement, the cell was incubated for 2 days in 5 mM 4-phenylbutyrate. 30 μ M quercetin was added where indicated by the box. Further stimulation by forskolin (10 μ M) is also shown. The holding potential was -60 mV.

Figure 7 is a recording illustrating the effect of genistein on G551D-CFTR expressed in a *Xenopus* oocyte. Current was measured with the two-electrode voltage clamp technique. G551D-CFTR was injected in oocyte. Current was first stimulated with forskolin (10 μ M) and isobutylmethylxanthine (IBMX; 2 mM). Genistein (50 μ M) was added as indicated. The right panel shows current voltage relations recorded after treatment with forskolin and IBMX (F/I) and after treatment with genistein (F/I+Geni). A voltage ramp from -130 mV to +70 mV was applied and current was recorded during the two conditions.

Figure 8 is a recording illustrating the effect of quercetin on nasal potential difference (PD) measurement in a healthy human volunteer. Amiloride (50 μ M) was added to block sodium transport as indicated. Conditions were rendered chloride free (Cl free) and chloride secretion was stimulated with isoproterenol (iso; 5 μ M). Quercetin (querc; 10 μ M) was added as indicated.

Figure 9 is a recording illustrating the effect of apigenin and kaempferol on nasal PD in mice. Chloride secretion was stimulated with isoproterenol (iso; 5 μ M), and amiloride (50 μ M) was added to block sodium transport as indicated. Under chloride-free conditions (Cl free), apigenin (50 μ M, left panel) and kaempferol (kaemp, 50 μ M, right panel) were added as indicated.

Figure 10 is a recording illustrating the effect of genistein, with and without 4-phenylbutyrate, on chloride current in JME cells. The recording was performed at 0 mV holding potential with a 17:150 mM chloride gradient from bath to pipette. The bottom trace is from an untreated cell and the top trace is from a cell that had been incubated in 5 mM 4-phenylbutyrate (4-PB) for two days. Forskolin (10 μ M) and genistein (30 μ M) were added as indicated.

Figures 11A-11C are a whole cell patch clamp recording (Figure 11A) and graphs (Figures 11B and 11C) illustrating the effect of forskolin and genistein on HeLa cells infected with a G551D-CFTR-containing adenovirus. Cells were stimulated with forskolin (10 μ M) and genistein (30 μ M), as indicated. The fit of the data with the Goldman equation is shown by the line in Figure 11B. A current variance to mean current plot is shown in Figure 11C.

Figure 12A and 12B illustrate the use of representative flavenoids for the treatment of CF patients. Figure 12A shows a recording from a patient with the genotype G551D/ Δ F508. Amiloride, chloride free solution and isoproterenol were added as indicated. The addition of genistein, as indicated, hyperpolarized nasal PD. Figure 12B is a graph illustrating the average responses of nasal PD to genistein and quercetin of four CF patients with the G551D mutation. The filled bars show, for comparison, the respective responses in healthy subjects.

Figures 13A-13C illustrate the effect of additional representative flavenoids and isoflavenoids on chloride current in epithelial cells. Figure 13A is a graph showing the stimulation of transepithelial chloride currents by resveratrol (100 μ M), flavanone (100 μ M), flavone (200 μ M), apigenin (20 μ M), apigenin 7-O-neohesperidoside (30 μ M), kaempferol (20 μ M), fisetin (100 μ M), quercetin (30 μ M), rutin (30 μ M), genistein (30 μ M), daidzein (50 μ M), biochanin A (100 μ M) and prunetin (100 μ M) in Calu-3 monolayers. Experiments were performed in the presence of 10 μ M forskolin. Stimulated currents are plotted relative to forskolin stimulated increase (forskolin stimulated currents are 100%). Figure 13B is a recording showing the effect of 7,4'-Dihydroxyflavone on chloride current in unstimulated tissue. This recording shows a dose-dependent stimulation of transepithelial short-circuit current (I_{sc}) across Calu-3 monolayers by 7,4'-Dihydroxyflavone. Increasing concentrations of 7,4'-Dihydroxyflavone (as indicated in μ M) were added to mucosal side and dose-dependently stimulated chloride currents. Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2 mV. Figure 13C is a recording illustrating the effect of trimethoxy-apigenin. This recording shows dose-dependent stimulation of transepithelial short-circuit current (I_{sc}) across Calu-3 monolayers by

trimethoxy-apigenin. Increasing concentrations of trimethoxy-apigenin (as indicated in μM) were added to mucosal side and dose-dependently stimulated chloride currents. Experiment was performed on unstimulated tissue. Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2 mV.

Figure 14 is a recording illustrating the dose-dependent stimulation of transepithelial short-circuit current (I_{sc}) across Calu-3 monolayers by resveratrol. Increasing concentrations of resveratrol (as indicated in μM) were added to the mucosal perfusion and dose-dependently increased chloride currents. For comparison, currents were further stimulated by serosal addition of 20 μM forskolin. Stimulated chloride current was completely blocked by addition of the chloride channel blocker DPC (5 mM). Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2 mV.

Figure 15 is a recording showing L-ascorbic acid and genistein stimulation of transepithelial short-circuit current (I_{sc}) across Calu-3 monolayers. Ascorbic acid (100 μM) was added as indicated. For comparison, ascorbic acid-stimulated chloride current was subsequently stimulated by the cAMP elevating agonist forskolin (20 μM , serosal). The CFTR activator genistein (20 mM) was then added to the mucosal perfusion as indicated. Stimulated current was completely blocked by addition of the chloride channel blocker DPC (5 mM), added as indicated. Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2 mV.

Figure 16 is a recording showing L-Ascorbic acid and kaempferol stimulation of transepithelial short-circuit current (I_{sc}) across Calu-3 monolayers. 100 μM ascorbic acid and forskolin (fsk, 20 μM , serosal) were added as indicated. The CFTR activator kaempferol (20 μM) was subsequently added, as indicated. Stimulated current was completely blocked by addition of the chloride channel blocker DPC (5 mM). Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2 mV.

Figure 17 is a recording illustrating the effect of L-ascorbic acid on nasal potential difference in human subjects. Amiloride, chloride-free solution and

L-ascorbic acid (100 μ M) were added to the luminal perfusate in the nose, as indicated. The β -adrenergic agonist isoproterenol was also added as indicated. Stimulation was reversed by washing out drugs with NaCl Ringer solution.

Figure 18 is a recording illustrating the stimulation of transepithelial short-circuit current (Isc) across Calu-3 monolayers by addition of 10, 100 and 300 μ M dehydroascorbic acid. Currents were recorded with a serosal-to-mucosal chloride gradient at 0 mV and pulses were obtained at 2mV.

Figure 19 is a recording illustrating the stimulatory effect of 20 μ M genistein on transepithelial short-circuit current (Isc) across 31EG4 mammary epithelial monolayers. Na currents were blocked by mucosal addition of amiloride (10 mM), and chloride currents were further stimulated by forskolin (20 μ M, serosal), as indicated. Currents were recorded in symmetrical NaCl Ringers solution at 0 mV and pulses were obtained at 2 mV.

DETAILED DESCRIPTION OF THE INVENTION

As noted above, the present invention is generally directed to compositions and methods for the treatment of diseases characterized by defective chloride transport in epithelial tissues, including cystic fibrosis, and diseases with excessive accumulation of mucus, including cystic fibrosis, chronic bronchitis and asthma. It has been found, within the context of the present invention, that certain flavones and isoflavones, as well as other polyphenolic compounds, are capable of stimulating CFTR-mediated chloride transport in epithelial tissues (*e.g.*, tissues of the airways, intestine, pancreas and other exocrine glands) in a cyclic-AMP independent manner. Ascorbic acid and derivatives thereof may also, or alternatively, be used within such methods. It has further been found, within the context of the present invention, that such compounds stimulate chloride transport in cells with a mutated CFTR (*e.g.*, Δ F508-CFTR or G551D-CFTR). Such therapeutic compounds may be administered to patients afflicted with cystic fibrosis as described herein.

The term "flavones," as used herein refers to a compound based on the core structure of flavone:

**Flavone**

An "isoflavone" is an isomer of a flavone (*i.e.*, the phenyl moiety at position 2 is moved to position 3), and having the core structure shown below:

**Isoflavone**

Certain flavones and isoflavones have the structure:

or

wherein carbon atoms at positions 2, 3, 5, 6, 7, 8, 2', 3', 4', 5' and 6' are bonded to a moiety independently selected from the group consisting of hydrogen atoms, hydroxyl groups and methoxyl groups, and wherein X is a single bond or a double bond. Stereoisomers and glycoside derivatives of such polyphenolic compounds may also be used within the methods provided herein.

Many flavones are naturally-occurring compounds, but synthetic flavones and isoflavones are also encompassed by the present invention. A flavone or isoflavone may be modified to comprise any of a variety of functional groups, such as hydroxyl and/or ether groups. Preferred flavones comprise one or more hydroxyl groups, such as the trihydroxyflavone apigenin, the tetrahydroxyflavone kaempferol and the pentahydroxyflavone quercetin. Preferred isoflavones comprise one or more hydroxyl and/or methoxy groups, such as the methoxy, dihydroxy isoflavone biochanin A. Genistein is yet another preferred isoflavone for use within the methods provided herein.

Flavones and isoflavones for use within the context of the present invention have the ability to stimulate chloride transport in epithelial tissues. Such transport may result in secretion or absorption of chloride ions. The ability to stimulate chloride transport may be assessed using any of a variety of systems. For example, *in vitro* assays using a mammalian trachea or a cell line, such as the permanent airway cell line Calu-3 (ATCC Accession Number HTB55) may be employed. Alternatively, the ability to stimulate chloride transport may be evaluated within an *in vivo* assay employing a mammalian nasal epithelium. In general, the ability to stimulate chloride transport may be assessed by evaluating CFTR-mediated currents across a membrane by employing standard Ussing chamber (see Ussing and Zehrahn, *Acta. Physiol. Scand.* 23:110-127, 1951) or nasal potential difference measurements (see Knowles et al., *Hum. Gene Therapy* 6:445-

455, 1995). Within such assays, a flavone or isoflavone that stimulates a statistically significant increase in chloride transport at a concentration of about 1 - 300 μ M is said to stimulate chloride transport.

Within one *in vitro* assay, the level of chloride transport may be evaluated using mammalian pulmonary cell lines, such as Calu-3 cells, or primary bovine tracheal cultures. In general, such assays employ cell monolayers, which may be prepared by standard cell culture techniques. Within such systems, CFTR-mediated chloride current may be monitored in an Ussing chamber using intact epithelia. Alternatively, chloride transport may be evaluated using epithelial tissue in which the basolateral membrane is permeabilized with *Staphylococcus aureus* α -toxin, and in which a chloride gradient is imposed across the apical membrane (see Illek et al., *Am. J. Physiol.* 270:C265-75, 1996). In either system, chloride transport is evaluated in the presence and absence of a test compound (*i.e.*, a flavone or isoflavone), and those compounds that stimulate chloride transport as described above may be used within the methods provided herein.

Within another *in vitro* assay for evaluating chloride transport, cells are transfected with a chloride channel gene (*e.g.*, CFTR) having a mutation associated with cystic fibrosis. Any CFTR gene that is altered relative to the normal human sequence provided in SEQ ID NO:1, such that the encoded protein contains a mutation associated with cystic fibrosis, may be employed within such an assay. The most common disease-causing mutation in cystic fibrosis is a deletion of phenylalanine at position 508 in the CFTR protein (Δ F508-CFTR; SEQ ID NO:4). Accordingly, the use of a CFTR gene encoding Δ F508-CFTR is preferred. However, genes encoding other altered CFTR proteins (*e.g.*, G551D-CFTR; containing a glycine to aspartate point mutation at position 551; SEQ ID NO:6) may also be used. Cells such as NIH 3T3 fibroblasts may be transfected with an altered CFTR gene, such as Δ F508-CFTR, using well known techniques (see Anderson et al., *Science* 25:679-682, 1991). The effect of a compound on chloride transport in such cells may be evaluated by monitoring CFTR-mediated currents using the patch clamp method (see Hamill et al., *Pflugers Arch.* 391:85-100, 1981) with and without compound application.

Within another *in vitro* assay, a mutant CFTR may be microinjected into cells such as *Xenopus* oocytes. Chloride conductance mediated by the CFTR mutant in the presence and absence of a test compound may be monitored with the two electrode voltage clamp method (see Miledi et al., *Proc. R. Soc. Lond. Biol.* 218:481-484, 1983).

Alternatively, such assays may be performed using a mammalian trachea, such as a primary cow tracheal epithelium using the Ussing chamber technique as described above. Such assays are performed in the presence and absence of test compound to identify flavone and isoflavones that stimulate chloride transport.

Any of the above assays may be performed following pretreatment of the cells with a substance that increases the concentration of CFTR mutants in the plasma membrane. Such substances include chemical chaperones, which support correct trafficking of the mutant CFTR to the membrane, and compounds that increase expression of CFTR in the cell (*e.g.*, transcriptional activators). A "chemical chaperone," as used herein is any molecule that increases trafficking of proteins to a cell membrane. More specifically, a chemical chaperone within the context of the present invention increases trafficking of a mutant CFTR (*e.g.*, the Δ 508-CFTR and/or G551D-CFTR) to the membrane by a statistically significant amount. Chemical chaperones for use herein include, but are not limited to, glycerol, dimethylsulfoxide, trimethylamine N-oxide, taurin, methylamine and deoxyspergualin (see Brown et al., *Cell Stress Chaperones* 1:117-125, 1996; Jiang et al., *Amer J. Physiol.-Cell Physiol.* 44:C171-C178, 1998). Compounds that increase expression of CFTR in the cell include 4-phenylbutyrate (Rubenstein et al., *J. Clin. Invest.* 100:2457-2465, 1997) and sodium butyrate (Cheng et al., *Am. J. Physiol.* 268:L615-624, 1995). Other compounds that increase the level of CFTR in the plasma membrane (by increasing correct trafficking and/or expression of the CFTR) may be readily identified using well known techniques, such as immunohistochemical techniques, to evaluate effects on levels of plasma membrane CFTR.

In vivo, chloride secretion may be assessed using measurements of nasal potential differences in a mammal, such as a human or a mouse. Such measurements may be performed on the inferior surface of the inferior turbinate following treatment of the mucosal surface with a test compound during perfusion with the sodium transport blocker amiloride in chloride-free solution. The nasal potential difference is measured as the electrical potential measured on the nasal mucosa with respect to a skin electrode placed on a slightly scratched skin part (*see* Alton et al., *Eur. Respir. J.* 3:922-926, 1990) or with respect to a subcutaneous needle (*see* Knowles et al., *Hum. Gene Therapy* 6:445-455, 1995). Nasal potential difference is evaluated in the presence and absence of test compound, and those compounds that results in a statistically significant increase in nasal potential difference stimulate chloride transport.

Compounds as provided herein may generally be used to chloride transport within any of a variety of CFTR-expressing epithelial cells. CFTR is expressed in may epithelial cells, including intestinal, airway, pancreas, gallbladder, sweat duct, salivary gland and mammary epithelia. All such CFTR-expressing organs are subject to stimulation my the compounds provided herein.

As noted above, any flavone or isoflavone that stimulates chloride transport within at least one of the above assays may be used for therapy of cystic fibrosis, other diseases characterized by abnormally high mucus accumulation in the airways or intestinal disorders such as constipation. Preferred therapeutic compounds include flavones and isoflavones that occur naturally in plants and are part of the human diet. Preferred compounds include genistein (4',5,7-trihydroxyisoflavone), as well as quercetin (3,3',4',5,7-pentahydroxyflavone), apigenin (4'5,7-trihydroxyflavone), kaempferol (3,4',5,7-tetrahydroxyflavone) and biochanin A (4'-methoxy-5,7-dihydroxyisoflavone), as depicted below:

**Genistein****Biochanin A****Kaempferol****Apigenin****Quercetin**

5

Other suitable therapeutic compounds may be identified using the representative assays as described herein. Additional representative flavones and isoflavones include flavanone, flavone, dihydroxyflavone, trimethoxy-apigenin, apigenin 7-O-neohesperidoside, fisetin, rutin, daidzein and prunetin. Representative flavones and isoflavones are summarized in Tables I and II.

Genistein, quercetin, apigenin, kaempferol, biochanin A and other flavones and isoflavones may generally be prepared using well known techniques, such as those described by Shakhova et al., *Zh. Obshch. Khim.* 32:390, 1962; Farooq et al., *Arch. Pharm.* 292:792, 1959; and Ichikawa et al., *Org. Prep. Prog. Int.* 14:183, 1981. Alternatively, such compounds may be commercially available (e.g., from Indofine Chemical Co., Inc., Somerville, NJ or Sigma-Aldrich, St. Louis, MO). Further modifications to such compounds may be made using conventional organic chemistry techniques, which are well known to those of ordinary skill in the art.

As noted above, other polyphenolic compounds may be used within the methods provided herein. For example, trihydroxystilbenes such as resveratrol (trans-3,5,4'-trihydroxystilbene) may be employed. Resveratrol is a polyphenolic compound having the following structure:

- Other compounds that may be used within the methods provided herein are ascorbic acid and derivatives thereof. Such compounds include L-ascorbic acid (L-xyloascorbic acid), dehydroascorbic acid (L-threo-2,3-
- 5 Hexodiulosonic acid γ -lactone) and salts of the foregoing acids.

L-Ascorbic Acid

Dehydroascorbic Acid

- 10 Within certain preferred embodiments, ascorbic acid or a derivative thereof is used in combination with a polyphenolic compound as described above. Certain representative combinations include ascorbic acid and one or more flavenoids and/or isoflavenoids (such as genistein and ascorbic acid; and kaempferol and ascorbic acid). Ascorbic acid may generally be used to treat or
- 15 prevent genetic loss of chloride secretory function (*e.g.*, cystic fibrosis), as well as other related loss or reduced chloride secretory function (*e.g.*, intestinal constipation, dry eye syndrome and obstructive airway diseases).

For *in vivo* use, a therapeutic compound as described herein is generally incorporated into a pharmaceutical composition prior to administration. Within such compositions, one or more therapeutic compounds as described herein are present as active ingredient(s) (*i.e.*, are present at levels sufficient to provide a statistically significant effect on nasal potential difference, as measured using a representative assay as provided herein). A pharmaceutical composition comprises one or more such compounds in combination with any physiologically acceptable carrier(s) and/or excipient(s) known to those skilled in the art to be suitable for the particular mode of administration. In addition, other pharmaceutically active ingredients (including other therapeutic agents) may, but need not, be present within the composition.

Within certain methods provided herein, a flavone or isoflavone may be combined with a substance that increases the concentration of CFTR mutants in the plasma membrane of a cell. As noted above, such substances include chemical chaperones, which support correct trafficking of the mutant CFTR to the membrane, and compounds that increase expression of CFTR in the membrane. These substances may be contained within the same pharmaceutical composition or may be administered separately. Preferred chemical chaperones include glycerol, dimethylsulfoxide, trimethylamine N-oxide, taurin, methylamine and deoxyspergualin, and compounds that increase expression of CFTR in the membrane include 4-phenylbutyrate and sodium butyrate. The use of flavenoid and/or isoflavenoid compounds, as described herein, in combination with such substances may increase mutant CFTR activity, and ameliorate symptoms of cystic fibrosis.

Administration may be achieved by a variety of different routes. One preferred route is oral administration of a composition such as a pill, capsule or suspension. Such compositions may be prepared according to any method known in the art, and may comprise any of a variety of inactive ingredients. Suitable excipients for use within such compositions include inert diluents (which may be solid materials, aqueous solutions and/or oils) such as calcium or sodium carbonate, lactose, calcium or sodium phosphate, water, arachis oil, peanut oil liquid paraffin

10/2/07 5:23:50

or olive oil; granulating and disintegrating agents such as maize starch, gelatin or acacia and/or lubricating agents such as magnesium stearate, stearic acid or talc. Other inactive ingredients that may, but need not, be present include one or more suspending agents (*e.g.*, sodium carboxymethylcellulose, methylcellulose, hydroxypropylmethylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia), thickeners (*e.g.*, beeswax, paraffin or cetyl alcohol), dispersing or wetting agents, preservatives (*e.g.*, antioxidants such as ascorbic acid), coloring agents, sweetening agents and/or flavoring agents.

A pharmaceutical composition may be prepared with carriers that protect active ingredients against rapid elimination from the body, such as time release formulations or coatings. Such carriers include controlled release formulations, such as, but not limited to, microencapsulated delivery systems, and biodegradable, biocompatible polymers, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, polyorthoesters, polylactic acid and others known to those of ordinary skill in the art.

Particularly preferred are methods in which the therapeutic compound(s) are directly administered as a pressurized aerosol or nebulized formulation to the patient's lungs via inhalation. Such formulations may contain any of a variety of known aerosol propellants useful for endopulmonary and/or intranasal inhalation administration. In addition, water may be present, with or without any of a variety of cosolvents, surfactants, stabilizers (*e.g.*, antioxidants, chelating agents, inert gases and buffers). For compositions to be administered from multiple dose containers, antimicrobial agents are typically added. Such compositions are also generally filtered and sterilized, and may be lyophilized to provide enhanced stability and to improve solubility.

Pharmaceutical compositions are administered in an amount, and with a frequency, that is effective to inhibit or alleviate the symptoms of cystic fibrosis and/or to delay the progression of the disease. The effect of a treatment may be clinically determined by nasal potential difference measurements as described herein. The precise dosage and duration of treatment may be determined empirically using known testing protocols or by testing the compositions in model

systems known in the art and extrapolating therefrom. Dosages may also vary with the severity of the disease. A pharmaceutical composition is generally formulated and administered to exert a therapeutically useful effect while minimizing undesirable side effects. In general, an oral dose ranges from about 200 mg to about 1000 mg, which may be administered 1 to 3 times per day. Compositions administered as an aerosol are generally designed to provide a final concentration of about 10 to 50 μM at the airway surface, and may be administered 1 to 3 times per day. It will be apparent that, for any particular subject, specific dosage regimens may be adjusted over time according to the individual need.

As noted above, a pharmaceutical composition may be administered to a mammal to stimulate chloride transport, and to treat cystic fibrosis. Patients that may benefit from administration of a therapeutic compound as described herein are those afflicted with cystic fibrosis. Such patients may be identified based on standard criteria that are well known in the art, including the presence of abnormally high salt concentrations in the sweat test, the presence of high nasal potentials, or the presence of a cystic fibrosis-associated mutation. Activation of chloride transport may also be beneficial in other diseases that show abnormally high mucus accumulation in the airways, such as asthma and chronic bronchitis. Similarly, intestinal constipation may benefit from activation of chloride transport by a flavone or isoflavone as provided herein.

Summary of Sequence Listing

SEQ ID NO:1 is a DNA sequence encoding human CFTR.

SEQ ID NO:2 is an amino acid sequence of human CFTR.

SEQ ID NO:3 is a DNA sequence encoding human CFTR with the ΔF508 mutation.

SEQ ID NO:4 is an amino acid sequence of human CFTR with the ΔF508 mutation.

SEQ ID NO:5 is a DNA sequence encoding human CFTR with the G551D mutation.

SEQ ID NO:6 is an amino acid sequence of human CFTR with the G551D mutation.

The following Examples are offered by way of illustration and not by
5 way of limitation.

0902346-104704

EXAMPLES

Example 1

5 Stimulation of Chloride Transport by Representative
 Flavones and Isoflavones in Airway Cells

This Example illustrates the use of the representative compounds apigenin, quercetin and biochanin A to enhance chloride secretion in Calu-3 human pulmonary cultures or in primary bovine tracheal cultures.

10 A Calu-3 cell monolayer was prepared in an Ussing chamber as described by Illek et al., *Am. J. Physiol.* 270:C265-275, 1996. The basolateral membrane was permeabilized with α -toxin and a chloride gradient was applied across the apical membrane as a driving force (*see* Illek et al, *Am. J. Physiol.* 270:C265-C275, 1996). The tissue was first stimulated with cAMP (100 μ M), and
 15 then with a representative flavone or isoflavone.

As shown in Figures 1 and 2, subsequent addition of apigenin or quercetin further stimulated chloride current. Figure 1 illustrates the short circuit current across the Calu-3 cell monolayer before and after addition of apigenin (50 μ M). Figure 2 illustrates the effect of quercetin (30 μ M) on chloride current across a
 20 Calu-3 monolayer. In both cases, the flavone stimulated chloride current beyond the stimulation achieved by cAMP.

Figure 3 illustrates the results of a related experiment to evaluate the dose-dependent stimulation of transepithelial chloride secretion by quercetin across a primary bovine tracheal epithelium. The epithelial cells were first treated with
 25 amiloride (50 μ M), and then with quercetin at the indicated concentrations. The dose-response relation yielded a half maximal stimulation at 12.5 μ M. At high concentrations of quercetin, the current was blocked. Current was fully inhibited by the CFTR channel blocker diphenylcarboxylate (DPC, 5 mM).

To evaluate the effect of biochanin A, a Calu-3 cell monolayer was
 30 prepared and permeabilized as described above. The tissue was first stimulated with forskolin (Fsk, 10 μ M). The effect of biochanin A (Bio, 100 and 300 μ M) on

short-circuit current (I_{sc}) across the Calu-3 monolayer was evaluated in an Ussing chamber. As shown in Figure 4, biochanin A further stimulated chloride secretion.

5

Example 2

Activation of Mutant CFTR by Representative Flavones and Isoflavones

This Example illustrates the use of the representative compounds apigenin, quercetin and genistein to activate $\Delta F508$ -CFTR and G551D-CFTR in different cell types.

10

A cell-attached single channel patch clamp recording was obtained from a 3T3 cell expressing $\Delta F508$ -CFTR as described by Hamill et al., *Pflugers Arch.* 391:85-100, 1981 and Fischer and Machen, *J. Gen. Physiol.* 104:541-566, 1994. As shown in Figure 5, stimulation of the cell with 10 μM forskolin did not activate $\Delta F508$ -CFTR channel, but addition of genistein (50 μM) or apigenin (50 μM , where indicated by boxes) induced $\Delta F508$ -CFTR channel openings, and removal of these compounds inactivated the channels. The holding potential was 75 mV, and channel openings were upward.

15

Figure 6 presents a whole cell patch clamp recording on an airway epithelial cell homozygous for $\Delta F508$ -CFTR (cell type: JME cell, *see* Jeffersen et al., *Am. J. Physiol.* 259:L496-L505, 1990). Before the measurement, the cell was incubated for 2 days in 5 mM 4-phenylbutyrate to enhance $\Delta F508$ -CFTR expression in the plasma membrane (Rubenstein & Zeitlin, *Ped. Pulm. Suppl.* 12:234, 1995). Measurements were performed as described by Fischer et al., *J. Physiol. Lond.* 489:745-754, 1995. Addition of 30 μM quercetin activated chloride current in the whole cell mode, which was further stimulated by forskolin. The holding potential was -60 mV.

20

25

The effect of genistein on chloride current in a *Xenopus* oocyte expressing G551D-CFTR was measured with the two-electrode voltage clamp technique (*see* Miledi et al., *Proc. R. Soc. Lond. Biol.* 218:481-484, 1983). G551D-CFTR (2 ng in 50 nL of water) was injected into the oocyte. Current was first stimulated with forskolin (10 μM) and isobutylmethylxanthine (IBMX; 2 mM).

30

Genistein (50 μM) was found to further activate chloride currents. As shown in Figure 7, genistein increased conductance and shifted reversal potential to the right, which is indicative of a stimulated chloride current.

5

Example 3

Effect of Representative Flavones on Nasal Potential Difference

This Example illustrates the *in vivo* use of quercetin, apigenin and kaempferol to activate the nasal potential difference in humans and mice.

10

The effect of quercetin on nasal potential difference (PD) measurement in a healthy human volunteer was measured as described by Knowles et al., *Hum. Gene Therapy* 6:445-455, 1995. Under conditions where sodium transport was blocked with amiloride (50 μM) and chloride secretion was stimulated under chloride-free conditions with isoproterenol (5 μM), quercetin (10 μM) stimulated nasal PD further (Figure 8).

15

The effect of apigenin and kaempferol on nasal PD in mice was evaluated using a method similar to that employed for measurements in humans, except that a plastic tube of approximately 0.1 mm diameter was used as an exploring nasal electrode. The plastic tube was perfused with test solutions at approximately 10 $\mu\text{L}/\text{min}$. After blocking sodium transport with amiloride (50 μM) and during stimulation of chloride secretion with isoproterenol (iso; 5 μM) under chloride-free conditions, apigenin (50 μM , left panel) and kaempferol (kaemp, 50 μM , right panel) further stimulated nasal PD.

20

These results show that the representative flavenoids quercetin, apigenin, kaempferol and biochanin A stimulate chloride transport across epithelial tissues derived from the airways *in vitro*, and across nasal epithelium *in vivo*. The results also show that the CFTR mutants ΔF508 and G551D can be activated by the representative compounds genistein and apigenin.

25

30

Example 4

Effect of Genistein on Chloride Current in Cells Expressing a Mutant CFTR

This Example illustrates the ability of the representative isoflavone genistein to activate chloride current in cells expressing a mutant CFTR.

5 In one experiment, genistein was used in combination with 4-phenylbutyrate. Chloride current was measured in JME cells (human nasal epithelial cell line homozygous for the $\Delta 508$ mutation of CFTR; see Jefferson et al., *Am. J. Physiol.* 259:L496-505, 1990). The recording was performed at 0 mV holding potential with a 17:150 mM chloride gradient from bath to pipette. Under
10 these conditions, the recorded current, shown in Figure 10, is chloride current (Illek and Fischer, *Am. J. Physiol. (Lung Cell. Mol. Physiol.)*:L902-910, 1998). The bottom trace in Figure 10 is from an untreated cell. Neither forskolin (10 μ M nor genistein (30 μ M activated current. The top tracing in Figure 10 is from a cell that
15 had been incubated in 5 mM 4-phenylbutyrate (4-PB) for two days (Rubenstein et al., *J. Clin. Invest.* 100:2457-2465, 1997). After 4-PB treatment, chloride current was stimulated by forskolin (by on average 30.3 ± 19.4 pS/pF, n=6), and further activated by genistein (to an average 105 ± 84 pS/pF) in a CF cell with the $\Delta 508$ -CFTR mutation. These results further demonstrate the ability of a flavenoid compound to optimize chloride currents elicited in CF cells by other means.

20 Within another experiment, HeLa cells infected with the G551D-CFTR-containing adenovirus were investigated in the patch clamp mode. Stimulation of the cell with forskolin (10 μ M) stimulated only a very small current (Figures 11A and 11B). On average, forskolin-stimulated conductance was 9.5 ± 5 pS/pF (n=4). Additional stimulation with genistein (30 μ M) stimulated significant
25 chloride currents, which were time- and voltage-independent (Figure 11B) and well fitted with the Goldman equation (line in Figure 11B; Illek and Fischer, *Am. J. Physiol. (Lung Cell. Mol. Physiol.)*:L902-910, 1998), which are characteristics of CFTR-mediated currents. Average forskolin + genistein-activated conductance was 120 ± 30 pS/pF (n=4). Current variance to mean current plot (Figure 11C) were
30 used to calculate the average open probability (P_o shown on top of axis) of the population of channels carrying the total current (as described in Illek and Fischer,

*Am. J. Physiol. (Lung Cell. Mol. Physiol.):*L902-910, 1998). During forskolin stimulation, maximal P_o reached was 0.04 (open circles) and after additional stimulation with genistein P_o reached a maximum of 0.42 in this recording. On average, after forskolin stimulation, $P_o = 0.05 \pm 0.02$ and after forskolin + genistein stimulation $P_o = 0.54 \pm 0.12$. For comparison, wild type CFTR expressed in HeLa cells and recorded under the same conditions resulted in $P_o = 0.36 \pm 0.05$ (n=3) after forskolin stimulation and $P_o = 0.63 \pm 0.16$ after forskolin + genistein treatment.

10

Example 5

Effect of Representative Flavones on Nasal Potential Difference in CF Patients

This Example illustrates the *in vivo* use of quercetin and genistein to activate the nasal potential difference in CF patients bearing the G551D mutation.

Measurements were performed on patients as described by Alton et al., *Eur. Respir. J.* 3:922-926, 1990; Illek and Fischer, *Am. J. Physiol. (Lung Cell. Mol. Physiol.):*L902-910, 1998; and Knowles et al., *Hum. Gene Therapy* 6:445-455, 1995). The results are presented in Figures 12A and 12B. Figure 12A shows a recording from a patient with the genotype G551D/ Δ F508. Initial treatment with amiloride and chloride free solution had the purpose to isolate and amplify the chloride selective potentials. Addition of the beta-adrenergic agonist isoproterenol showed no effect, which is typical for CF patients (Knowles et al., *Hum. Gene Therapy* 6:445-455, 1995). However, addition of genistein hyperpolarized nasal PD. Average responses of nasal PD to genistein and quercetin of four CF patients with the G551D mutation are shown in Figure 12B (open bars). The filled bars show for comparison the respective responses in healthy subjects. The genotypes of the 4 CF patients were: two G551D/ Δ F508, one G551D/G551D and one G551D/unknown. Responses are most likely due to the G551D mutation because the homozygous G551D patient responded not different compared to the heterozygous G551D patients. Genistein and quercetin responses of nasal PD in CF patients were significant ($p < 0.05$).

0992345 10101
T040T 5F2350

These results demonstrate that CFTR mutations are sensitive to flavenoid treatment, and provide additional evidence for therapeutic benefit of such compounds for the treatment of cystic fibrosis.

5

Example 6

Effect of Additional Representative Polyphenolic Compounds on Epithelial Cell Chloride Currents

This Example illustrates the effect of further flavenoids and
10 isoflavenoids on chloride currents in airway epithelial cells.

Airway epithelial cells were prestimulated with 10 μM forskolin. The percent increase in chloride current was then determined following treatment with a series of polyphenolic compounds. Figure 13A summarizes the stimulatory effect of these compounds. On average, chloride currents were further stimulated
15 by resveratrol (100 μM) to 135%, by flavanone (100 μM) to 140%, by flavone (200 μM) to 128%, by apigenin (20 μM) to 241%, by apigenin 7-O-neohesperidoside (30 μM) to 155%, by kaempferol (20 μM) to 182%, by fisetin (100 μM) to 108%, by quercetin (30 μM) to 169%, by rutin (30 μM) to 149%, by genistein (30 μM) to 229%, by daidzein (50 μM) to 162%, by biochanin A (100
20 μM) to 139% and by prunetin (100 μM) to 161%.

The stimulatory effect of 7,4'-Dihydroxyflavone is shown in Figure 13B. Addition of 7,4'-Dihydroxyflavone to the mucosal perfusion dose-dependently stimulated transepithelial C1 currents in unstimulated Calu-3 monolayers. This experiment was performed using unstimulated tissue.

25 The stimulatory effect of trimethoxy-apigenin is shown in Figure 13C. Addition of trimethoxy-apigenin to the mucosal perfusion dose-dependently stimulated transepithelial C1 currents in unstimulated Calu-3 monolayers. Kinetic analysis is depicted on the right panel and estimated half maximal stimulatory dose was 11.7 μM .

30 These results indicate that a variety of polyphenolic compounds stimulate chloride currents in epithelial cells.

Effect of Resveratrol on Chloride Currents

5

10

Example 8

Effect of Ascorbic Acid and Dehydroascorbic Acid on Chloride Currents

20

25

30

The stimulatory effect of L-ascorbic acid is also shown in Figure 16. Addition of 100 μ M L-ascorbic acid to the mucosal or serosal perfusion very effectively stimulated transepithelial chloride currents in unstimulated Calu-3 monolayers. For comparison, ascorbic acid-stimulated chloride currents were stimulated by the cAMP elevating agonist forskolin (20 μ M, serosal). Under these stimulated conditions kaempferol further hyperstimulated chloride currents. The stimulated chloride current was completely blocked by the chloride channel blocker DPC (5 mM).

The stimulatory effect of dehydroascorbic acid is shown in Figure 18. Addition of dehydroascorbic acid at 10, 100 or 300 μ M to the mucosal and serosal perfusion effectively stimulated transepithelial chloride currents in unstimulated Calu-3 monolayers. Stimulated Cl currents returned to baseline after 5-15 min.

Example 9

Effect of Ascorbic Acid on Chloride Currents *in vivo*

This Example illustrates the stimulatory effect of ascorbic acid on human nasal potential difference.

Nasal potential difference measurement was performed on a human volunteer according to a protocol by Knowles et al., *Hum. Gene Therapy* 6:445-455, 1995. Addition of L-ascorbic acid (100 μ M) to the luminal perfusate in the nose (in the presence of amiloride (blocks Na currents) and in chloride-free solution) hyperpolarized nasal potential difference (PD) by 6.3 mV (Figure 17). Addition of the β -adrenergic agonist isoproterenol further hyperpolarized nasal PD. Stimulation was reversed by washing out drugs with NaCl Ringer solution. These results demonstrate the ability of ascorbic acid to stimulate chloride transport in epithelia in humans.

Example 10Effect of Genistein on Chloride Currents in Mammary Epithelia

This Example illustrates the stimulatory effect of genistein in mammary epithelial cells.

5 The stimulation of transepithelial short-circuit current (I_{sc}) across 31EG4 mammary epithelial monolayers by addition of 20 μ M genistein is shown in Figure 19. Na currents were blocked by mucosal addition of amiloride (10 mM). Chloride currents were further stimulated by forskolin (20 μ M, serosal). Currents were recorded in symmetrical NaCl Ringers solution at 0 mV and pulses were
10 obtained at 2 mV.

From the foregoing, it will be appreciated that, although specific embodiments of the invention have been described herein for the purpose of illustration, various modifications may be made without deviating from the spirit
15 and scope of the invention. Accordingly, the invention is not limited except as by the appended claims.
